About this manual

This manual describes the System 200V Counter module FM 250 from VIPA. Here you may find every information for commissioning and operation.

Overview

Chapter 1: Basics and Assembly
The focus of this chapter is on the introduction of the VIPA System 200V. Here you will find the information required to assemble and wire a controller system consisting of System 200V components. Besides the dimensions the general technical data of System 200V will be found.

Chapter 2: Hardware description
Here the hardware components of the FM 250-1BA00 are described. The technical data are at the end of the chapter.

Chapter 3: Deployment
This chapter provides information to the configuration and the various counter modes of the Counter module FM 250 are described.
Objective and contents
This manual describes the System 200V Counter module FM 250-1BA00 from VIPA. It contains a description of the construction, project implementation and usage. This manual is part of the documentation package with order number HB97E_FM and relevant for:

<table>
<thead>
<tr>
<th>Product</th>
<th>Order number</th>
<th>as of state:</th>
</tr>
</thead>
<tbody>
<tr>
<td>FM 250</td>
<td>VIPA 250-1BA00</td>
<td>HW 01</td>
</tr>
</tbody>
</table>

Target audience
The manual is targeted at users who have a background in automation technology.

Structure of the manual
The manual consists of chapters. Every chapter provides a self-contained description of a specific topic.

Guide to the document
The following guides are available in the manual:
• an overall table of contents at the beginning of the manual
• an overview of the topics for every chapter

Availability
The manual is available in:
• printed form, on paper
• in electronic form as PDF-file (Adobe Acrobat Reader)

Icons
Important passages in the text are highlighted by following icons and headings:

Danger!
Immediate or likely danger.
Personal injury is possible.

Attention!
Damages to property is likely if these warnings are not heeded.

Note!
Supplementary information and useful tips.
Safety information

Applications conforming with specifications

The FM 250 is constructed and produced for:
• all VIPA System 200V components
• communication and process control
• general control and automation applications
• industrial applications
• operation within the environmental conditions specified in the technical data
• installation into a cubicle

Danger!
This device is not certified for applications in
• in explosive environments (EX-zone)

Documentation

The manual must be available to all personnel in the
• project design department
• installation department
• commissioning
• operation

The following conditions must be met before using or commissioning the components described in this manual:

• Hardware modifications to the process control system should only be carried out when the system has been disconnected from power!

• Installation and hardware modification only by properly trained personnel.

• The national rules and regulations of the respective country must be satisfied (installation, safety, EMC ...)

Disposal

National rules and regulations apply to the disposal of the unit!
Chapter 1 Basics and Assembly

Overview
The focus of this chapter is on the introduction of the VIPA System 200V. Here you will find the information required to assemble and wire a controller system consisting of System 200V components. Besides the dimensions the general technical data of System 200V will be found.

Safety Information for Users

Handling of electrostatic sensitive modules

VIPA modules make use of highly integrated components in MOS-Technology. These components are extremely sensitive to over-voltages that can occur during electrostatic discharges. The following symbol is attached to modules that can be destroyed by electrostatic discharges.

![Symbol for electrostatic sensitive equipment]

The Symbol is located on the module, the module rack or on packing material and it indicates the presence of electrostatic sensitive equipment. It is possible that electrostatic sensitive equipment is destroyed by energies and voltages that are far less than the human threshold of perception. These voltages can occur where persons do not discharge themselves before handling electrostatic sensitive modules and they can damage components thereby, causing the module to become inoperable or unusable.

Modules that have been damaged by electrostatic discharges can fail after a temperature change, mechanical shock or changes in the electrical load. Only the consequent implementation of protection devices and meticulous attention to the applicable rules and regulations for handling the respective equipment can prevent failures of electrostatic sensitive modules.

Shipping of electrostatic sensitive modules

Modules must be shipped in the original packing material.

Measurements and alterations on electrostatic sensitive modules

When you are conducting measurements on electrostatic sensitive modules you should take the following precautions:

- Floating instruments must be discharged before use.
- Instruments must be grounded.

Modifying electrostatic sensitive modules you should only use soldering irons with grounded tips.

Attention!

Personnel and instruments should be grounded when working on electrostatic sensitive modules.
System conception

Overview

The System 200V is a modular automation system for assembly on a 35mm profile rail. By means of the peripheral modules with 4, 8 and 16 channels this system may properly be adapted matching to your automation tasks.

Components

The System 200V consists of the following components:

- **Head modules** like CPU and bus coupler
- **Periphery modules** like I/O, function und communication modules
- **Power supplies**
- **Extension modules**

Head modules

With a head module CPU respectively bus interface and DC 24V power supply are integrated to one casing.

Via the integrated power supply the CPU respectively bus interface is power supplied as well as the electronic of the connected periphery modules.

Periphery modules

The modules are direct installed on a 35mm profile rail and connected to the head module by a bus connector, which was mounted on the profile rail before.

Most of the periphery modules are equipped with a 10pin respectively 18pin connector. This connector provides the electrical interface for the signaling and supplies lines of the modules.
Power supplies

With the System 200V the DC 24V power supply can take place either externally or via a particularly for this developed power supply.

The power supply may be mounted on the profile rail together with the System 200V modules. It has no connector to the backplane bus.

Expansion modules

The expansion modules are complementary modules providing 2- or 3-wire connection facilities.

The modules are not connected to the backplane bus.

Structure/dimensions

- Profile rail 35mm
- Dimensions of the basic enclosure:
  1-tier width: (HxWxD) in mm: 76x25.4x74 in inches: 3x1x3
  2-tier width: (HxWxD) in mm: 76x50.8x74 in inches: 3x2x3

Installation

Please note that you can only install head modules, like the CPU, the PC and couplers at slot 1 or 1 and 2 (for double width modules).

<p>| | |</p>
<table>
<thead>
<tr>

<tr>
<td>[3]</td>
<td>Periphery module</td>
</tr>
</tbody>
</table>

Note

Information about the max. number of pluggable modules and the max. current at the backplane bus can be found in the "Technical Data" of the according head module.

Please install modules with a high current consumption directly beside the head module.

EasyConn from
VIPA)
Installation

General
The modules are each installed on a 35mm profile rail and connected via a bus connector. Before installing the module the bus connector is to be placed on the profile rail before.

Profile rail
For installation the following 35mm profile rails may be used:

<table>
<thead>
<tr>
<th>Order number</th>
<th>Label</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>290-1AF00</td>
<td>35mm profile rail</td>
<td>Length 2000mm, height 15mm</td>
</tr>
<tr>
<td>290-1AF30</td>
<td>35mm profile rail</td>
<td>Length 530mm, height 15mm</td>
</tr>
</tbody>
</table>

Bus connector
System 200V modules communicate via a backplane bus connector. The backplane bus connector is isolated and available from VIPA in of 1-, 2-, 4- or 8tier width.

The following figure shows a 1tier connector and a 4tier connector bus:

The bus connector is to be placed on the profile rail until it clips in its place and the bus connections look out from the profile rail.

<table>
<thead>
<tr>

</tbody>
</table>
The following figure shows the installation of a 4-tier width bus connector in a profile rail and the slots for the modules. The different slots are defined by guide rails.

![Diagram of bus connector installation](image)

**Assembly regarding the current consumption**

- Use bus connectors as long as possible.
- Sort the modules with a high current consumption right beside the head module. In the service area of www.vipa.com a list of current consumption of every System 200V module can be found.
Please regard the allowed environmental temperatures:

- horizontal assembly: from 0 to 60°C
- vertical assembly: from 0 to 40°C
- lying assembly: from 0 to 40°C

The horizontal assembly always starts at the left side with a head module, then you install the peripheral modules beside to the right.

You may install up to 32 peripheral modules.

---

**Please follow these rules during the assembly!**

- Turn off the power supply before you install or remove any modules!
- Make sure that a clearance of at least 60mm exists above and 80mm below the middle of the profile rail.
- Every row must be completed from left to right and it has to start with a head module.

[1] Head module (double width)
[2] Head module (single width)
[3] Peripheral modules

- Modules are to be installed side by side. Gaps are not permitted between the modules since this would interrupt the backplane bus.
- A module is only installed properly and connected electrically when it has clicked into place with an audible click.
- Slots after the last module may remain unoccupied.

---

**Note!**

Information about the max. number of pluggable modules and the max. current at the backplane bus can be found in the "Technical Data" of the according head module.

Please install modules with a high current consumption directly beside the head module.
Assembly procedure

- Install the profile rail. Make sure that a clearance of at least 60mm exists above and 80mm below the middle of the profile rail.

- Press the bus connector into the profile rail until it clips securely into place and the bus-connectors look out from the profile rail. This provides the basis for the installation of your modules.

- Start at the outer left location with the installation of your head module and install the peripheral modules to the right of this.

- Insert the module that you are installing into the profile rail at an angle of 45 degrees from the top and rotate the module into place until it clicks into the profile rail with an audible click. The proper connection to the backplane bus can only be guaranteed when the module has properly clicked into place.

Attention!
Power must be turned off before modules are installed or removed!
Demounting and module exchange

1. Remove if exists the wiring to the module, by pressing both locking lever on the connector and pulling the connector.

2. The casing of the module has a spring loaded clip at the bottom by which the module can be removed.

3. The clip is unlocked by pressing the screwdriver in an upward direction.

4. Withdraw the module with a slight rotation to the top.

5. Attention!

Power must be turned off before modules are installed or removed!
Please regard that the backplane bus is interrupted at the point where the module was removed!
Wiring

Overview
Most peripheral modules are equipped with a 10pole or a 18pole connector. This connector provides the electrical interface for the signaling and supply lines of the modules.
The modules carry spring-clip connectors for interconnections and wiring. The spring-clip connector technology simplifies the wiring requirements for signaling and power cables.
In contrast to screw terminal connections, spring-clip wiring is vibration proof. The assignment of the terminals is contained in the description of the respective modules.
You may connect conductors with a diameter from 0.08mm² up to 2.5mm² (max. 1.5mm² for 18pole connectors).
The following figure shows a module with a 10pole connector.

![Diagram of a module with a 10pole connector with labels: 1. Locking lever, 2. Pin no. at the module, 3. Pin no. at the connector, 4. Wiring port, 5. Opening for screwdriver.]

Note!
The spring-clip is destroyed if you push the screwdriver into the wire port! Make sure that you only insert the screwdriver into the square hole of the connector!
Wiring procedure

- Install the connector on the module until it locks with an audible click. For this purpose you press the two clips together as shown. The connector is now in a permanent position and can easily be wired.

The following section shows the wiring procedure from top view.

- Insert a screwdriver at an angle into the square opening as shown.
- Press and hold the screwdriver in the opposite direction to open the contact spring.

- Insert the stripped end of the wire into the round opening. You can use wires with a diameter of 0.08mm² to 2.5mm² (1.5mm² for 18pole connectors).

- By removing the screwdriver the wire is connected safely with the plug connector via a spring.

Note!
Wire the power supply connections first followed by the signal cables (inputs and outputs).
Installation guidelines

General
The installation guidelines contain information about the interference free deployment of System 200V systems. There is the description of the ways, interference may occur in your control, how you can make sure the electromagnetic digestibility (EMC), and how you manage the isolation.

What means EMC?
Electromagnetic digestibility (EMC) means the ability of an electrical device, to function error free in an electromagnetic environment without being interferenced res. without interfering the environment.
All System 200V components are developed for the deployment in hard industrial environments and fulfill high demands on the EMC. Nevertheless you should project an EMC planning before installing the components and take conceivable interference causes into account.

Possible interference causes
Electromagnetic interferences may interfere your control via different ways:
- Fields
- I/O signal conductors
- Bus system
- Current supply
- Protected earth conductor

Depending on the spreading medium (lead bound or lead free) and the distance to the interference cause, interferences to your control occur by means of different coupling mechanisms.
One differs:
- galvanic coupling
- capacitive coupling
- inductive coupling
- radiant coupling
Basic rules for EMC

In the most times it is enough to take care of some elementary rules to guarantee the EMC. Please regard the following basic rules when installing your PLC.

- Take care of a correct area-wide grounding of the inactive metal parts when installing your components.
  - Install a central connection between the ground and the protected earth conductor system.
  - Connect all inactive metal extensive and impedance-low.
  - Please try not to use aluminum parts. Aluminum is easily oxidizing and is therefore less suitable for grounding.

- When cabling, take care of the correct line routing.
  - Organize your cabling in line groups (high voltage, current supply, signal and data lines).
  - Always lay your high voltage lines and signal res. data lines in separate channels or bundles.
  - Route the signal and data lines as near as possible beside ground areas (e.g. suspension bars, metal rails, tin cabinet).

- Proof the correct fixing of the lead isolation.
  - Data lines must be laid isolated.
  - Analog lines must be laid isolated. When transmitting signals with small amplitudes the one sided laying of the isolation may be favorable.
  - Lay the line isolation extensively on an isolation/protected earth conductor rail directly after the cabinet entry and fix the isolation with cable clamps.
  - Make sure that the isolation/protected earth conductor rail is connected impedance-low with the cabinet.
  - Use metallic or metalized plug cases for isolated data lines.

- In special use cases you should appoint special EMC actions.
  - Wire all inductivities with erase links.
  - Please consider luminescent lamps can influence signal lines.

- Create a homogeneous reference potential and ground all electrical operating supplies when possible.
  - Please take care for the targeted employment of the grounding actions. The grounding of the PLC is a protection and functionality activity.
  - Connect installation parts and cabinets with the System 200V in star topology with the isolation/protected earth conductor system. So you avoid ground loops.
  - If potential differences between installation parts and cabinets occur, lay sufficiently dimensioned potential compensation lines.
Isolation of conductors

Electrical, magnetically and electromagnetic interference fields are weakened by means of an isolation, one talks of absorption. Via the isolation rail, that is connected conductive with the rack, interference currents are shunt via cable isolation to the ground. Hereby you have to make sure, that the connection to the protected earth conductor is impedance-low, because otherwise the interference currents may appear as interference cause.

When isolating cables you have to regard the following:

- If possible, use only cables with isolation tangle.
- The hiding power of the isolation should be higher than 80%.
- Normally you should always lay the isolation of cables on both sides. Only by means of the both-sided connection of the isolation you achieve high quality interference suppression in the higher frequency area. Only as exception you may also lay the isolation one-sided. Then you only achieve the absorption of the lower frequencies. A one-sided isolation connection may be convenient, if:
  - the conduction of a potential compensating line is not possible
  - analog signals (some mV res. µA) are transferred
  - foil isolations (static isolations) are used.
- With data lines always use metallic or metalized plugs for serial couplings. Fix the isolation of the data line at the plug rack. Do not lay the isolation on the PIN 1 of the plug bar!
- At stationary operation it is convenient to strip the insulated cable interruption free and lay it on the isolation/protected earth conductor line.
- To fix the isolation tangles use cable clamps out of metal. The clamps must clasp the isolation extensively and have well contact.
- Lay the isolation on an isolation rail directly after the entry of the cable in the cabinet. Lead the isolation further on to the System 200V module and don't lay it on there again!

Please regard at installation!

At potential differences between the grounding points, there may be a compensation current via the isolation connected at both sides. Remedy: Potential compensation line.
General data

Structure/dimensions
- Profile rail 35mm
- Peripheral modules with recessed labelling
- Dimensions of the basic enclosure:
  1 tier width: (HxWxD) in mm: 76x25.4x74 in inches: 3x1x3
  2 tier width: (HxWxD) in mm: 76x50.8x74 in inches: 3x2x3

Reliability
- Wiring by means of spring pressure connections (CageClamps) at the front-facing connector, core cross-section 0.08 ... 2.5mm² or 1.5mm² (18pole plug)
- Complete isolation of the wiring when modules are exchanged
- Every module is isolated from the backplane bus
- ESD/Burst acc. IEC 61000-4-2 / IEC 61000-4-4 (to level 3)
- Shock resistance acc. IEC 60068-2-6 / IEC 60068-2-27 (1G/12G)
- Class of protection IP20

Environmental conditions
- Operating temperature: 0 ... +60°C
- Storage temperature: -25 ... +70°C
- Relative humidity: 5 ... 95% without condensation
- Ventilation by means of a fan is not required
Chapter 2  Hardware description

Overview
Here the hardware components of the FM 250-1BA00 are described.
The technical data are at the end of the chapter.

Properties

FM 250
250-1BA00

- 2 channels with each 32Bit /
  4 channels with each 16Bit (depending on the mode)
- DC 24V supply voltage via front and via backplane bus
- free configurable DC 24V outputs (max.1A)
- Counter and compare registers are loaded by means of a control byte
- Standard up-down counter with a resolution of 32Bit or 16Bit
- Compare and auto-reload functions
- Different modes for encoder pulses
- Pulse-width measurements and frequency measurements

Note!
The following information is only applicable to counter modules with
order no.: VIPA 250-1BA00 and a revision level 5 and higher.

Structure

Functionality

The counter module accepts the signals from transducers connected to the module and processes these pulses in accordance with the selected mode of operation. The module has 2/4 channels with a data resolution of 32/16Bit each. These modules provide 40 counter modes and two 24V outputs they are controlled in accordance with the selected mode.

Chapter 3 Deployment

Overview
This chapter provides information to the configuration and the various counter modes of the Counter module FM 250 are described.

Data input / output

Access to the counter module

The module has 2/4 channels with a resolution of 32/16Bit each. You may use parameters to specify the mode for each channel res. channel pair. The pin assignment for the channel depends upon the selected mode (see description of modes).

10 data bytes are required for the data input and output. Data output to a counter channel requires 10Byte, for example for defaults or for comparison values. In the latter case Byte 9 (control) is used to initiate a write operation into the required counter register. The respective values are transferred into the counter registers when they are toggled (0 → 1).

The 10. byte (status byte) controls the behavior of the counter during a restart of the next higher master module. You may set the counter level to retentive by means of a combination of Bits 0 and 1; i.e. the original counter level will not be reset when the next higher master module restarts.

The following combinations are possible:

- Bit 0 = 1, Bit 1 = 0  counter value is retentive during restart
- Bit 0 = x, Bit 1 = 1  counter value is reset during restart (default)

You may check your settings at any time by reading Byte 10 of the output data.

Configuration parameters

The configuration parameters consist of 2Byte. You use these bytes to define the operating mode of each channel by means of a mode number. This chapter contains a detailed description of the different modes further below. The different combinations of the various modes are available from the table on the next page. The procedure for the transfer of parameter bytes is available from the description for the System 200V bus coupler or the master system.

<td>revision level 11</td>
</tr>
<tr>
<td>Mode 6, 20-26</td>
<td>revision level 6/7</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Terminology:

**RES**
RESET signal that has to be LOW during the measuring process. A HIGH level (level triggered) erases one or both counters, depending on the selected mode.

**RES↑**
The counter is reset by the rising edge of this signal (edge triggered).

**CLK**
The clock signal from the connected transducer.

**Start or Stop**
A HIGH level starts or stops the counter. When the start level is active, the counter will start with the next CLK pulse that corresponds to the selected mode.

**DIR**
In mode 0 the level of the DIR signal determines the direction of the counting process.
LOW level: count up
HIGH level: count down
Auto Reload

The Auto Reload function transfers a user-defined value into the counter when the counter reaches the number contained in the compare register.

Compare Load

You may use the compare function to specify an stop value for the counter. Depending on the selected mode an output is activated or the counter is restarted when it reaches this value.

Gate

Gate signal enabling the counter.

Gate/R↑

The counter is reset by the rising edge of this signal. As long as the signal is at "1", the counter is released. 

(Gate = level triggered; R↑ = edge triggered)

Measurement gate

Status indicator of the counter activity - is set to a HIGH level after the 1. CLK signal and LOW level after the last CLK signal (mode 18 ... 19).

Pulse

The pulse width of the introduced signal is determined by means of the internal time base.

Fref

Reference or clock frequency that is set permanently to 50kHz in mode 6. The clock frequency "Fref" for counter modes 20-22, 39-42 is programmable:

<table>

</tr>
</tbody>
</table>
## Counter modes

### Mode 0  
**32Bit counter**

2x 32Bit Counter. You determine the direction by means of the DIR input (IN3 or IN6). Every rising or falling edge of the input clock signal increments or decrements the counter. During the counting process the RES signal must be at a LOW level. If the RES signal is at a HIGH level, the counter is cleared. When the counter reaches zero, output OUT of the respective counter is active for a minimum period of 100ms, even if the counter should continue counting. If the counter stops at zero, the output remains active.

  - Counter 0/1
  - Counter 2/3
**Up counter**

In mode 0, a LOW level at the DIR input configures the counter for counting up.

Timing diagram of the counter 0/1 example:

![Up counter timing diagram](image)

**Down counter**

In mode 0, a HIGH level at the DIR input configures the counter for counting down.

Timing diagram of the counter 0/1 example:

![Down counter timing diagram](image)
In mode 1 you may configure an encoder for one of the channels. Depending on the direction of rotation this encoder will increment or decrement the internal counter with every falling edge. The RES input has to be at a LOW level during the counting process. A HIGH level clears the counter. When the counter reaches zero, output OUT of the respective counter is active for a minimum period of 100ms, even if the counter continues counting. If the counter stops at zero the output remains active.

Pin assignment access to counter
**Up counter**

Every falling edge of the signal at input A increments the counter if input B is at HIGH level at this moment.

Timing diagram for the counter 0/1 example:

---

**Down counter**

Every rising edge of the signal at input A decrements the internal counter if input B is at HIGH level at this moment.

Timing diagram for the counter 0/1 example:
**Mode 3**

**Encoder 2 edges**

Every rising or falling edge of the signal at input A changes the counter by 1. The direction of the count depends on the level of the signal applied to input B. RES has to be at a LOW level during the counting process. A HIGH level clears the counter. When the counter reaches zero, output OUT of the respective counter is active for a minimum period of 100ms, even if the counter continues counting. If the counter stops at zero the output remains active.

[Diagram of pin assignment and counter access]
**Up counter**  
The counter is incremented by the rising edge of signal A if input B is at a LOW level or by the falling edge of input A when input B is at a HIGH level.  
Timing diagram for the counter 0/1 example:

**Down-counter**  
The counter is decremented by the rising edge of signal A if input B is at a HIGH level or by the falling edge of input A when input B is at a LOW level.  
Timing diagram for the counter 0/1 example:
Every rising or falling edge at inputs A or B increments or decrements the counter. The direction depends on the level applied to the other input (B or A). RES has to be at a LOW level during the counting process. A HIGH level clears the counter. When the counter reaches zero, output OUT of the respective counter is active for a minimum period of 100ms, even if the counter continues counting. If the counter stops at zero, the output remains active.
The counter is incremented when a rising edge is applied to B while input A is at a HIGH level or if a falling edge is applied to B when input A is at a LOW level. Alternatively it is also incremented when a rising edge is applied to A when input B is at a LOW level or by a falling edge at A when input B is at a HIGH level.

**Up counter**

Timing diagram for the counter 0/1 example:

The counter is decremented when a rising edge is applied to B while input A is at a LOW level or if a falling edge is applied to B when input A is at a HIGH level. Alternatively it is also decremented when a rising edge is applied to A when input B is at a HIGH level or by a falling edge at input A when input B is at a LOW level.

**Down counter**

Timing diagram for counter 0/1 example:
Mode 8 ... 11  
**two input counter function**

In this mode each channel provides 2 counters of 16Bit each. The rising edge of the input clock CLK x increments or decrements the respective counter. In this mode each counter can also be preset to a certain value by means of a control bit. Outputs are not available. A RESET is also not available. The following combinations are possible for every channel:

- **Mode 8** - counter 0/1 up, counter 2/3 up
- **Mode 9** - counter 0/1 down, counter 2/3 up
- **Mode 10** - counter 0/1 up, counter 2/3 down
- **Mode 11** - counter 0/1 down, counter 2/3 down

**Pin assignment access to counter**

**Timing diagram**

Below follows a timing diagram depicting an example of counter 0 and counter 1 in mode 8:
In mode 12 and mode 13 you can implement a 32Bit counter that is controlled by a gating signal (Gate). The direction of counting depends on the selected mode. Every rising edge of the input signal increments or decrements the counter provided that the GATE signal is at HIGH level. RES has to be LOW during the counting process. A HIGH level clears the counter. When the counter reaches the value that was previously loaded into the compare register, output OUT is set active for a minimum period of 100ms while the counter continues counting.

**Mode 12 - 32Bit counter up + gate with compare**

**Mode 13 - 32Bit counter down + gate with compare**

**Timing diagram**

Below follows an example of a timing diagram of counter 0/1 in mode 12:
Mode 14 and 15
32Bit counter with gate and auto reload

Modes 14 and 15 operate in the same manner as mode 12 and 13 with the addition of an Auto Reload function. The "Auto Reload" is used to define a value in the load register that is used to preset the counter automatically when it reaches the compare value.

A HIGH pulse applied to RES clears the counter to 0000 0000. A HIGH level applied to GATE enables the counter so that is incremented/decremented by every rising edge of the CLK signal. As long as GATE is HIGH, the counter will count every rising edge of the signal applied to CLK until the count is one less than the value entered into COMPARE. The next pulse overwrites the counter with the value contained in the load register. This process continues until GATE is set to a LOW level. When an auto reload occurs, the status of the respective output changes.

The RES signal only resets the counter but not the outputs.

Mode 14 - 32Bit counter up + gate with compare and auto reload
Mode 15 - 32Bit counter down + gate with compare and auto reload

Pin assignment
access to counter
Example

This example is intended to explain the operation of the counters in mode 14 and 15.

A HIGH pulse applied to RES clears the counter to 0000 0000. A HIGH level applied to GATE enables the counter. As long as GATE is HIGH the counter will count every rising edge of the signal applied to CLK until the count is one less than the value entered into COMPARE. In this example the counter counts to 0000 0004 followed immediately by an auto reload, i.e. the counter is preset to the contents of the load register (in this case 0000 0002). The state of output OUT 0 changes every time an auto reload is executed.

In this example the counter counts from 0000 0002 to 0000 0004 as long as the GATE input is at a HIGH level.

Every load operation changes the status of output OUT 0.
In this mode it is possible to determine the frequency of the signal that is applied to the CLK input. Counter 0/1 is provided with a reference signal by means of DE7 and a gate time that is controlled indirectly by the value \( n \) to determine the duration for which counter 2/3 is enabled. The value of \( n \) has a range from 1 to \( 2^{32}-1 \) and it is loaded into the COMPARE register.

When enabled by the rising edge of the signal applied to Start, counter 0/1 counts reference pulses of the reference clock generator from the first rising edge of the CLK signal.

During this time counter 2/3 counts every rising edge of the CLK signal. Both counters are stopped when counter 0/1 reaches the COMPARE value or when a HIGH level is applied to Stop. You may calculate the frequency by means of the formula shown below.

This mode can not be combined with other modes!

![Diagram of pin assignment and access to counter]

**Frequency calculation**

When the measurement has been completed you may calculate the frequency as follows:

\[
\text{Frequency} = \frac{F_{\text{ref}} \cdot m}{n}
\]

where

- \( F_{\text{ref}} \): reference frequency (supplied in DE7 with control bit 7)
- \( m \): counter 2/3 contents (number of CLK pulses)
- \( n \): number of reference frequency pulses in counter 0/1 (equal to COMPARE, if the operation was not terminated prematurely by means of Stop)
Timing diagram

Example

Quantity = 1 000 000 pulses
Reference frequency = 1MHz

Using a frequency of 1MHz and 1 000 000 pulses will return 1Hz, i.e. when the measurement is completed, counter 2/3 contains the frequency directly - no conversion is required.

Note!
Counter 2/3 will indicate the exact frequency if you choose $F_{ref}$ and $n$ so that the formula returns 1Hz precisely.
**Mode 17 period measurement**

This mode is used to determine the average period of n measuring intervals of a signal that is connected to the CLK input. For this purpose you supply a reference clock to counter 2/3 by means of DE7 and indirectly a gate time defined by the value of n for which counter 2/3 is enabled. The value of n has a range from 1 to \(2^{32}-1\) and it is loaded into the COMPARE register. 

The measurement period begins when a rising edge is applied to Start. During this period counter 2/3 counts reference pulses from the reference clock generator starting with the first rising edge of the CLK signal. 

In the mean time counter 0/1 counts every rising edge of the CLK signal. Both counters are stopped when the count in counter 0/1 reaches the Compare value or when Stop is set to a HIGH level. You may then calculate the average period by means of the formula shown below.

*This mode can not be combined with other modes!*

Parameter

Reference frequency

- 0 : 10 MHz
- 1 : 1 MHz
- 2 : 100 kHz
- 3 : 10 kHz
Period calculation

When the measurement has been completed, you may calculate the period as follows:

\[
Period = \frac{m}{F_{ref} \cdot n}
\]

where \( F_{ref} \): reference frequency (supplied in DE7 with control bit 7)

\( m \): contents of counter 2/3 (counts reference clock pulses)

\( n \): number of CLK pulses in counter 0/1 (corresponds to COMPARE, provided it was not terminated prematurely by Stop)

Timing diagram:
The operation of mode 18 is similar to mode 16. The only difference is the manner in which OUT 0 and OUT 1 are controlled. In this case OUT 0 is only activated when the counting operation starts and it is deactivated when counting ends, i.e. OUT 0 provides an indication of the internal gate. OUT 1 provides the inverted status of the gate.

This mode can not be combined with other modes!

Pin assignment
access to counter

When the measurement has been completed, you may calculate the frequency as follows:

\[
\text{Frequency} = \frac{F_{\text{ref}} \cdot m}{n}
\]

where
- \(F_{\text{ref}}\): reference frequency (supplied in DE7 with control bit 7)
- \(m\): contents of counter 2/3 (CLK pulse count)
- \(n\): number of pulses of the reference frequency in counter 0/1 (corresponds to COMPARE provided it was not terminated prematurely by Stop)
Note!
Counter 2/3 will indicate the exact frequency if you choose \( F_{ref} \) and \( n \) so that the formula returns 1Hz precisely.

For example when the applied frequency is 1MHz and the number of pulses is 1 000 000 the result will be 1Hz, i.e. counter 2/3 contains the precise frequency after the measurement - this does not require further conversion.

Timing diagram:

Example

Pulse count = 1 000 000
Reference frequency = 1MHz
Mode 19
period measurement with gate output

The operation of mode 19 is identical to mode 17. The only difference is the manner in which OUT 0 and OUT 1 are controlled. Other than for mode 17, OUT 0 is only activated when the counting operation starts and it is deactivated when counting ends, i.e. OUT 0 provides an indication of the internal gate. OUT 1 provides the inverted status of the gate.

This mode can not be combined with other modes!

Data to module

Compare (quantity) = comparison

Parameter
Reference frequency
0 : 10 MHz
1 : 1 MHz
2 : 100 kHz
3 : 10 kHz
**Period calculation**

When the measurement has been completed you may calculate the mean period as follows:

\[
\text{Period} = \frac{m}{F_{\text{ref}} \cdot n}
\]

where
- \(F_{\text{ref}}\): reference frequency (supplied in DE7 with control bit 7)
- \(m\): contents of counter 2/3 (reference clock pulse count)
- \(n\): number of CLK pulses in counter 0/1 (corresponds to COMPARE, provided it was not terminated prematurely by Stop)

**Timing diagram:**

- IN1 (RES)
- IN3 (Start)
- IN4 (Stop)
- IN2 (CLK)
- Counter 0/1
- Counter 2/3
- Out0 (Meas. Gate internal)
- Out1 (Meas. Gate internal)
The pulse width of a signal connected to the CLK input is determined by means of an internal time base and saved. The measurement is started with the falling edge of the input signal and it is stopped by the rising edge of the input. This saves the value in 20μs units in a buffer from where it may be retrieved (corresponds to Fref = 50kHz).

Input DIR determines the counting direction of the counter. If DIR is at a LOW level the counter counts up. A HIGH level lets the counter count down.

The input RES has to be at a LOW level. A HIGH at this input would clear the counter.

With the rising edge of the signal pulse, a result is transferred into the DA area; the result remains available until it is overwritten by the next new result.

Signals Out 0 or Out 1 are not modified.

### Up counter

The RES signal and the DIR signal are reset. The measurement is started by the falling edge at input PULSE and the counter is clocked up by the 50kHz clock. The rising edge of the signal at input PULSE terminates the count operation and the result is transferred into the result register. The result is available to the PLC. The value remains in the result register until a new measurement has been completed which overwrites the register.

![Up counter diagram]

### Down counter

The RES signal is reset and the DIR signal is placed at a HIGH level. The measurement is started by the falling edge at input PULSE and the counter is clocked down by the 50kHz clock. The rising edge of the signal at input PULSE terminates the count operation and the result is transferred into the result register. The result is available to the PLC. The value remains in the result register until a new measurement has been completed which overwrites the register.

![Down counter diagram]
Mode 20
pulse
measurements, pulse down

**prog. time base with direction control**

The pulse width of a signal that is applied to the PULSE input is determined by means of an internal time base. The measurement is started by the falling edge of the input signal and ends with the rising edge. The rising edge of the measured signal stores the resulting pulse width in units of $1/F_{ref}$, that may be retrieved again.

Input DIR controls the direction of the count. When DIR is held at a LOW level the counter counts up. When DIR is at a HIGH level the counter counts down.

RES has to be held at LOW during the counting operation. A HIGH level clears the counter.

$F_{ref}$ is programmable.

The OUT signal is not changed.

In mode 27, a HIGH level at the DIR input configures the counter for counting down.  
Timing diagram of the counter 0/1 example:

![Down counter timing diagram](image2)
Mode 28
Encoder 1 edge

In mode 28 you may configure an encoder for one of the channels. Depending on the direction of rotation this encoder will increment or decrement the internal counter with every falling edge. The rising edge of the signal Gate/R↑ resets the counter. During the count process, the signal Gate/R↑ has to be HIGH. When the signal Gate/R↑ becomes "0", the counter value remains valid. When the counter reaches zero, output OUT of the respective counter is active for a minimum period of 100ms, even if the counter continues counting. If the counter stops at zero the output remains active.

Pin assignment
access to counter
**Up counter**  
Every falling edge of the signal at input A increments the counter if input B is at HIGH level at this moment.  
Timing diagram for the counter 0/1 example:

```
Gate/R 0/1 (IN1)
B 0/1 (IN3)
A 0/1 (IN2)
Counter 0/1
```

**Down counter**  
Every rising edge of the signal at input A decrements the internal counter if input B is at HIGH level at this moment.  
Timing diagram for the counter 0/1 example:

```
Gate/R 0/1 (IN1)
B 0/1 (IN3)
A 0/1 (IN2)
Counter 0/1
```
Every rising or falling edge of the signal at input A changes the counter by 1. The direction of the count depends on the level of the signal applied to input B. The rising edge of the signal Gate/R↑ resets the counter. During the count process, the signal Gate/R↑ has to be HIGH. When the signal Gate/R↑ becomes "0", the counter value remains valid. When the counter reaches zero, output OUT of the respective counter is active for a minimum period of 100ms, even if the counter continues counting. If the counter stops at zero the output remains active.

**Up counter**  
The counter is incremented by the rising edge of signal A if input B is at a LOW level or by the falling edge of input A when input B is at a HIGH level.  
Timing diagram for the counter 0/1 example:

![Up counter timing diagram](image)

**Down counter**  
The counter is decremented by the rising edge of signal A if input B is at a HIGH level or by the falling edge of input A when input B is at a LOW level.  
Timing diagram for the counter 0/1 example:

![Down counter timing diagram](image)
Every rising or falling edge at inputs A or B increments or decrements the counter. The direction depends on the level applied to the other input (B or A). The rising edge of the signal Gate/R\textsuperscript{↑} resets the counter. During the count process, the signal Gate/R\textsuperscript{↑} has to be HIGH. When the signal Gate/R\textsuperscript{↑} becomes "0", the counter value remains valid. When the counter reaches zero, output OUT of the respective counter is active for a minimum period of 100ms, even if the counter continues counting. If the counter stops at zero, the output remains active.

Up counter

The counter is incremented when a rising edge is applied to B while input A is at a HIGH level or if a falling edge is applied to B when input A is at a LOW level. Alternatively it is also incremented when a rising edge is applied to A when input B is at a LOW level or by a falling edge at A when input B is at a HIGH level.

Timing diagram for the counter 0/1 example:

Down counter

The counter is decremented when a rising edge is applied to B while input A is at a LOW level or if a falling edge is applied to B when input A is at a HIGH level. Alternatively it is also decremented when a rising edge is applied to A when input B is at a HIGH level or by a falling edge at input A when input B is at a LOW level.

Timing diagram for counter 0/1 example:
In mode 31 and mode 32 you can implement a 32Bit counter that is controlled by a gating signal (Gate). The direction of counting depends on the selected mode. Every rising edge of the input signal increments or decrements the counter provided that the GATE signal is at HIGH level. A rising edge of RES\(^\uparrow\) clears the counter. When the counter reaches the value that was previously loaded into the compare register, output OUT is set active for a minimum period of 100ms while the counter continues counting.

**Mode 31 - 32Bit counter up + gate with compare**

**Mode 32 - 32Bit counter down + gate with compare**

### Timing diagram

Below follows an example of a timing diagram of counter 0/1 in mode 31:
Modes 33 and 34 operate in the same manner as mode 31 and 32 with the addition of an Auto Reload function. The "Auto Reload" is used to define a value in the load register that is used to preset the counter automatically when it reaches the compare value.

A rising edge of RES↑ clears the counter to 0000 0000. A HIGH level applied to GATE enables the counter so that is incremented/decremented by every rising edge of the CLK signal. As long as GATE is HIGH, the counter will count every rising edge of the signal applied to CLK until the count is one less than the value entered into COMPARE. The next pulse overwrites the counter with the value contained in the load register. This process continues until GATE is set to a LOW level. When an auto reload occurs, the status of the respective output changes.

The RES↑ signal only resets the counter but not the outputs.

**Mode 33 - 32Bit counter up + gate with compare and auto reload**

**Mode 34 - 32Bit counter down + gate with compare and auto reload**
Example

This example is intended to explain the operation of the counters in mode 33 and 34.

A rising edge of RES\(^↑\) clears the counter to 0000 0000. A HIGH level applied to GATE enables the counter. As long as GATE is HIGH the counter will count every rising edge of the signal applied to CLK until the count is one less than the value entered into COMPARE. In this example the counter counts to 0000 0004 followed immediately by an auto reload, i.e. the counter is preset to the contents of the load register (in this case 0000 0002). The state of output OUT 0 changes every time an auto reload is executed.

In this example the counter counts from 0000 0002 to 0000 0004 as long as the GATE input is at a HIGH level.
Every load operation changes the status of output OUT 0.
Mode 35
32Bit counter

You determine the direction by means of the DIR input (IN3 or IN6). Every rising or falling edge of the input clock signal increments or decrements the counter. During the count process, the signal Gate has to be HIGH. When the signal Gate becomes "0", the counter value remains valid. When the counter reaches zero, output OUT of the respective counter is active for a minimum period of 100ms, even if the counter should continue counting. If the counter stops at zero, the output remains active.

Counter 0/1 (channel 1)

Counter 2/3 (channel 2)
**Up counter**

In mode 35, a LOW level at the DIR input configures the counter for counting up.

Timing diagram of the counter 0/1 example:

```
Gate 0/1 (N1)  
(DIR 0/1 (N3)      
CLK 0/1 (N2)  
Counter 0/1  
```

**Down counter**

In mode 35, a HIGH level at the DIR input configures the counter for counting down.

Timing diagram of the counter 0/1 example:

```
Gate 0/1 (N1)  
(DIR 0/1 (N3)      
CLK 0/1 (N2)  
Counter 0/1  
```
Mode 36  
Encoder 1 edge

In mode 36 you may configure an encoder for one of the channels. Depending on the direction of rotation this encoder will increment or decrement the internal counter with every falling edge. During the count process, the signal Gate has to be HIGH. When the signal Gate becomes "0", the counter value remains valid. When the counter reaches zero, output OUT of the respective counter is active for a minimum period of 100ms, even if the counter continues counting. If the counter stops at zero the output remains active.

Pin assignment access to counter
**Up counter**

Every falling edge of the signal at input A increments the counter if input B is at HIGH level at this moment.

Timing diagram for the counter 0/1 example:

**Down counter**

Every rising edge of the signal at input A decrements the internal counter if input B is at HIGH level at this moment.

Timing diagram for the counter 0/1 example:
Mode 37
Encoder 2 edges

Every rising or falling edge of the signal at input A changes the counter by 1. The direction of the count depends on the level of the signal applied to input B. During the count process, the signal Gate has to be HIGH. When the signal Gate becomes "0", the counter value remains valid. When the counter reaches zero, output OUT of the respective counter is active for a minimum period of 100ms, even if the counter continues counting. If the counter stops at zero the output remains active.

Pin assignment
access to counter
The counter is incremented by the rising edge of signal A if input B is at a LOW level or by the falling edge of input A when input B is at a HIGH level. Timing diagram for the counter 0/1 example:

**Up counter**

The counter is decremented by the rising edge of signal A if input B is at a HIGH level or by the falling edge of input A when input B is at a LOW level. Timing diagram for the counter 0/1 example:

**Down counter**
**Mode 38**  
**Encoder 4 edges**

Every rising or falling edge at inputs A or B increments or decrements the counter. The direction depends on the level applied to the other input (B or A). During the count process, the signal Gate has to be HIGH. When the signal Gate becomes "0", the counter value remains valid. When the counter reaches zero, output OUT of the respective counter is active for a minimum period of 100ms, even if the counter continues counting. If the counter stops at zero, the output remains active.
**Up counter**

The counter is incremented when a rising edge is applied to B while input A is at a HIGH level or if a falling edge is applied to B when input A is at a LOW level. Alternatively it is also incremented when a rising edge is applied to A when input B is at a LOW level or by a falling edge at A when input B is at a HIGH level.

Timing diagram for the counter 0/1 example:

![Timing diagram for the counter 0/1 example](image)

**Down counter**

The counter is decremented when a rising edge is applied to B while input A is at a LOW level or if a falling edge is applied to B when input A is at a HIGH level. Alternatively it is also decremented when a rising edge is applied to A when input B is at a HIGH level or by a falling edge at input A when input B is at a LOW level.

Timing diagram for counter 0/1 example:

![Timing diagram for counter 0/1 example](image)
Mode 39 - 32Bit Counter up + Gate low active
Mode 40 - 32Bit Counter down + Gate low active
Mode 41 - 32Bit Counter up + Gate high active
Mode 42 - 32Bit Counter down + Gate high active

The modes 39 to 42 allow you to realize a 32Bit counter for each channel that is controlled via a low or high active gate signal (gate) and counts with an internal reference frequency.

The direction of counting depends on the selected mode. With rising edge of the pulse frequency the counter is incremented res. decremented by 1.

The rising edge of the signal RES resets the counter.
Fref is programmable.
The OUT signal is not changed.

2 : 100 kHz
3 : 10 kHz

DC 24V
Mode 39  
32Bit Counter up + Gate low active  
The rising edge of the signal RES↑ resets the counter. With the signal gate "0", the counter counts up with Fref.

Mode 40  
32Bit Counter down + Gate low active  
The rising edge of the signal RES↑ resets the counter. With the signal gate "0", the counter counts down with Fref.
Mode 41  32Bit Counter up + Gate high active
The rising edge of the signal $RES^\dagger$ resets the counter. With the signal gate "1", the counter counts up with $F_{ref}$.

Mode 42  32Bit Counter down + Gate high active
The rising edge of the signal $RES^\dagger$ resets the counter. With the signal gate "1", the counter counts down with $F_{ref}$.
